# INTRODUCTION

## The Standard Model (SM)

- Our best description of fundamental particles and three of the four forces: electromagnetic, weak, and strong (gravity is not included)
- Built on quantum field theory: matter particles (quarks, leptons) interact via force-carrying bosons ( $\gamma$ ,  $W^\pm$ ,  $Z$ , gluons)
- The Brout-Englert-Higgs mechanism (1964) was proposed to explain electroweak symmetry breaking and the origin of particle mass, predicting a new scalar boson, the Higgs boson
- Extremely well-tested: the SM has withstood decades of precision measurements at LEP, Tevatron, and the LHC

## Why Beyond the Standard Model (BSM)?

- The SM, despite its success, is known to be incomplete: it does not account for dark matter, neutrino masses, matter–antimatter asymmetry, or gravity
- Since the 2012 discovery, precision studies of the 125 GeV Higgs boson's couplings and production modes have continued, alongside searches for additional scalar states
- Large excesses across Run 1/Run 2 measurements (differential Higgs  $p_T$ , di-Higgs searches, top-associated Higgs production,  $VV$  resonances, multi-lepton final states) hint at physics beyond a single SM-like Higgs
- These excesses motivate extended Higgs-sector models 2HDM+S and Higgs triplet models collectively referred to here as HBSM (Higgs Beyond the Standard Model) scenario.

**4 July 2012:** ATLAS and CMS independently announced discovery of a new boson with mass  $\approx 125$  GeV, consistent with the long-sought SM Higgs boson completing the SM particle content.

# PHYSICS MOTIVATION (Multilepton Anomalies)

- Run 1 ATLAS data showed a cluster of large excesses across several distinct measurements: differential Higgs  $p_T$ , di-Higgs resonance searches, top-associated Higgs production, and  $VV$  resonance searches ( $V = Z, W^\pm$ ).
- These excesses motivated a simplified model: a heavy particle produced via gluon fusion and decaying as  $H \rightarrow Sh$ .
- Independently, multilepton final states across Run 2 and early Run 3 have shown a pattern of anomalies significances ranging from  $\sim 3\sigma$  to  $>5\sigma$  across five distinct final states
- That model predicts a scalar with mass  $150 \pm 5$  GeV, produced in association with a heavier state.
- This Analysis uses Run 3 ATLAS data alongside with phenomenological input to probe the Run 2 excesses and cross-check the predicted 152 GeV peak.
- This is the mass region this analysis targets searching for the same scalar in the multilepton final states, where the associated lepton gives an independent production handle and a different background composition than the inclusive diphoton channel.

# Models: 2HDM+S and Triplet

## 2HDM+S Model

- Heavy CP-even scalar  $H$  produced via ggF (top-quark loop, scaling factor  $\sim \beta_g$  relative to SM)
- $H$  decays to a pair of lighter scalars:  $H \rightarrow Sh$  or  $H \rightarrow S'h$ , with  $m_H = 250 \text{ GeV}$ ,  $m_S \approx 152 \text{ GeV}$
- Introduced to explain multi-lepton and diphoton excesses at the LHC ([von Buddenbrock et al.](#))
- Key coupling:  $\beta_g^2 \approx 1.38 \pm 0.22$ , giving  $\tan^2 \beta \approx 0.72 \pm 0.12$

## Triplet Model

- Charged/neutral triplet scalars ( $Y = 0$ ) produced via Drell-Yan:  $q\bar{q} \rightarrow W^* \rightarrow \Delta_{150}^0 \Delta_{150}^{\pm}$
- $\Delta_{150}^0 \rightarrow \gamma\gamma$ , consistent with the diphoton  $\approx 152 \text{ GeV}$  excess
- $\Delta_{150}^{\pm}$  decays dominantly to  $W\pm Z$

# Why $\gamma\gamma + 1\mu$ Channel

## Target Channels

$$\gamma\gamma + 0\ell + 1\tau$$

$$\gamma\gamma + 0\ell + 2\tau$$

$$\gamma\gamma + 1\ell + 1\tau$$

$$\gamma\gamma + 2\ell + 0\tau$$

$$\gamma\gamma + 1\mu + 0\tau_{had}$$

$$\gamma\gamma + 1\ell + 1b$$

## 2HDM+S decay chain

$$gg \rightarrow H \rightarrow (S \rightarrow \gamma\gamma)(S'/h \rightarrow X)$$

$m_H = 250 \text{ GeV}$ ,  $m_S \approx 152 \text{ GeV}$  benchmark; the diphoton resonance ( $S \rightarrow \gamma\gamma$ ) anchors event reconstruction.

- The companion scalar  $S'/h$  decays to  $b\bar{b}$ ,  $\tau^+\tau^-$  or  $WW^*$ , populating the different  $\ell/\tau/b$  categories in the table at left
- $\gamma\gamma + 1\mu + 0\tau_{had}$  isolates events where  $S'/h$  produces exactly one reconstructed muon, either prompt or from heavy-flavour decay, with no hadronic  $\tau$ , a clean, low-background slice of the decay chain
- Muons give a clean tag: low fake rates and high reconstruction purity, vs. electrons/jets faking leptons or  $\tau_{had}$  **misidentification**.
- $1\mu + 0\tau_{had}$  requirement strongly suppresses  $\gamma\gamma jets$  and Drell-Yan/diphoton continuum backgrounds
- Mass scan covers the low-mass  $S'/h$  region: H 250–400 GeV, S 150–275 GeV,  $S'/h$  95–125 GeV

# ANALYSIS STRATEGY: MASS REGIONS

## CR : Control Region (Low Sideband)

$$105 < m_{\gamma\gamma} < 120 \text{ GeV}$$

Data-driven scale-factor derivation for the irreducible  $V\gamma\gamma/t\bar{t}\gamma\gamma$  backgrounds.

## SR : Signal Region (blinded)

$$130 < m_{\gamma\gamma} < 200 \text{ GeV}$$

Background MC characterisation; encloses the expected signal at  $m_{\gamma\gamma} \approx 152$  GeV. Data blinded until unblinding approval.

## CR : Validation Region (High Sideband)

$$m_{\gamma\gamma} > 200 \text{ GeV}$$

Kinematic Data/MC validation of the CR-derived scale factor; independent cross-check, not used in the SF fit.

**Strategy:** derive SFs in sideband region, keep SR blinded — 120–130 GeV excluded to avoid the SM Higgs.

# Dataset, Monte Carlo Samples, and Event selection overview

## Dataset and Monte Carlo Samples

| Campaign | Data Taking | $\mathcal{L}$ [fb <sup>-1</sup> ] |
|----------|-------------|-----------------------------------|
| mc23a    | 2022        | 29.3                              |
| mc23d    | 2023        | 26.7                              |
| mc23e    | 2024        | 107.9                             |
| Combined | Run 3       | 163.9                             |

## Signal Samples

| Signal                 | Status            | Relevancy       |
|------------------------|-------------------|-----------------|
| $\gamma\gamma\tau\tau$ | Request Completed | Benchmark       |
| $\gamma\gamma + 1\ell$ | Request On-going  | High statistics |
| $\gamma\gamma + 2\ell$ | Request On-going  | High statistics |

## Background Samples

| Process                | Samples           | Why Relevant to $\gamma\gamma + 1\mu$                                             |
|------------------------|-------------------|-----------------------------------------------------------------------------------|
| $\gamma\gamma$ +jets   | FASTSIM + FULLSIM | Dominant background before muon selection. Fake muons entering the signal region. |
| $V\gamma\gamma$        | FULLSIM           | Prompt diphoton production with genuine leptons.                                  |
| $t\bar{t}\gamma\gamma$ | FULLSIM           | Top pair production with prompt muons. Contains additional jets and $b$ -jets.    |
| Single Higgs           | FULLSIM           | Associated Higgs production with similar final states.                            |

**$m_{\gamma\gamma} > 200\text{GeV}$**

CR Low-SB: Initial vs Final Event Yields  
 $105 < m_{\gamma\gamma} < 120 \text{ GeV}$  — Run 3,  $\mathcal{L} = 163.9 \text{ fb}^{-1}$

### CR: Low sideband mass

- $\gamma\gamma$ +jets is crushed by a factor of (15,000×) from ~298k initial down to 20 events, driven by the  $1\mu$  requirement killing jet-fake muons
- $V\gamma\gamma$  dominates the final composition (~97 events out of 120 total background) because its prompt muons survive selection efficiently.

CR High-SB: Initial vs Final Event Yields  
 $m_{\gamma\gamma} > 200 \text{ GeV}$  — Run 3,  $\mathcal{L} = 163.9 \text{ fb}^{-1}$

### CR: High sideband mass

- $V\gamma\gamma$  still dominates (~93 events) because it has a broad, slowly-falling  $m_{\gamma\gamma}$  spectrum.

# Scale Factor studies to normalize the irreducible backgrounds

$$\text{SF} = \frac{N_{\text{Data}} - N_{\gamma\gamma+\text{jets}} - N_{\text{SingleHiggs}}}{N_{t\bar{t}\gamma\gamma} + N_{V\gamma\gamma}}$$

*Derived from the full  $\gamma\gamma+1\mu$ -selected sideband yields per the internal collaboration 2024 Note.*

$$\sigma_N^2 = \sigma_{\text{data}}^2 + \sigma_{\gamma\gamma+\text{jets}}^2 + \sigma_{\text{SingleH}}^2, \tag{3}$$

$$\sigma_D^2 = \sigma_{t\bar{t}\gamma\gamma}^2 + \sigma_{V\gamma\gamma}^2. \tag{4}$$

The SF uncertainty is then obtained by combining the relative uncertainties on the numerator and denominator,

$$\sigma_{\text{SF}} = \text{SF} \sqrt{\left(\frac{\sigma_N}{N}\right)^2 + \left(\frac{\sigma_D}{D}\right)^2}. \tag{5}$$

Table 1: Per-year SF in the combined sideband after  $\gamma\gamma + 1\mu$  selection.

# Cutflow Results for Signal Region( 2022-2024)

Table 20: Cutflow — Signal Region (SR) — Blinded, combined.

| Selection Step                                                                                                               | Signal | $\gamma\gamma$ +jets | $V\gamma\gamma$ | $t\bar{t}\gamma\gamma$ | Single Higgs | Total Bkg. | Data    |
|------------------------------------------------------------------------------------------------------------------------------|--------|----------------------|-----------------|------------------------|--------------|------------|---------|
| 1) Initial Events                                                                                                            | 64.84  | 297,698.58           | 9,549.34        | 291.02                 | 1,294.53     | 308,833.46 | Blinded |
| 2) PASS_Trigger                                                                                                              | 64.84  | 297,698.58           | 9,549.34        | 291.02                 | 1,294.53     | 308,833.46 | Blinded |
| 3) Pass diphoton trigger matching                                                                                            | 64.84  | 297,698.58           | 9,549.34        | 291.02                 | 1,294.53     | 308,833.46 | Blinded |
| 4) Photon ID/Iso (Tight_FixedCutLoose)                                                                                       | 47.03  | 205,224.18           | 5,095.39        | 177.17                 | 943.06       | 211,439.81 | Blinded |
| 5) Photon eta & crack veto                                                                                                   | 46.75  | 204,290.60           | 5,067.83        | 176.26                 | 939.04       | 210,473.72 | Blinded |
| 6) $p_T(\gamma_1) > 35$ GeV & $p_T(\gamma_2) > 25$ GeV                                                                       | 46.74  | 203,915.70           | 5,045.74        | 176.17                 | 938.60       | 210,076.21 | Blinded |
| 7) $p_T(\gamma_1)/m_{\gamma\gamma} > 0.35$ & $p_T(\gamma_2)/m_{\gamma\gamma} > 0.25$                                         | 42.07  | 149,261.66           | 4,295.59        | 147.46                 | 841.69       | 154,546.40 | Blinded |
| 8) $m_{\gamma\gamma} > 105$ GeV                                                                                              | 41.79  | 89,583.05            | 1,496.51        | 97.99                  | 841.05       | 92,018.60  | Blinded |
| 9) $130 < m_{\gamma\gamma} < 200$ GeV                                                                                        | 41.73  | 31,682.35            | 596.74          | 44.96                  | 22.16        | 32,346.21  | Blinded |
| 10) $N_{b\text{-jets}} = 0$                                                                                                  | 40.52  | 31,238.84            | 582.48          | 9.51                   | 21.54        | 31,852.38  | Blinded |
| 11) $\gamma\gamma + 1\mu + \mu$ quality (Medium ID, $ d_0/\sigma_{d_0}  < 3$ , $ z_0 \sin \theta  < 0.5$ mm), $0e$ , $0\tau$ | 3.05   | 28.93                | 159.73          | 2.77                   | 0.22         | 191.66     | Blinded |

- Signal survives at 3.05 events by a factor ~20× loss from initial, but note this uses the  $\gamma\gamma\tau\tau$  benchmark; proper  $\gamma\gamma + 1\mu$  MC will improve this substantially.
- $V\gamma\gamma$  dominates strongly at ~160 events because the 70 GeV mass window is 4–5× wider than the sidebands.
- $\gamma\gamma$  +jets suppressed by ~10,000× to just 29 events the  $1\mu + 0\tau + 0e$  vetoes are doing the heavy lifting

# CR: Low sideband mass kinematic distributions (2022-2024)

14

- $p_T(\gamma\gamma)$  falls smoothly from  $\sim 50$  GeV. No anomalous high- $p_T$  tail.
- $\eta(\gamma\gamma)$  symmetric around zero. No detector asymmetry
- $\phi(\gamma\gamma)$  flat as expected for an azimuthally isotropic collision
- Leading  $p_T(\gamma_1)$  peaks higher than sub-leading consistent with the asymmetric  $p_T/m_{\gamma\gamma}$  cuts (0.35 vs 0.25)

- $p_T(\mu)$  peaks around 15–25 GeV then falls consistent with  $W \rightarrow \mu\nu$  kinematics dominating  $V\gamma\gamma$
- $\eta(\mu)$  covers  $|\eta| < 2.5$  as required good coverage across the tracker acceptance
- $\Delta(\gamma\gamma, \mu)$  peaks near  $\pi$ , the muon is back-to-back with the diphoton system, consistent with a resonant decay topology, not a photon-conversion or FSR configuration
- $|\Delta\phi(\mu, \text{MET})|$  is roughly flat, mixture of W-boosted (peak at 0) and unboosted topologies smearing across the range
- MET tail extends to  $\sim 150 \text{ GeV}$  dominated by  $W \rightarrow \mu\nu$  neutrinos in the  $V\gamma\gamma$  background

Before  $\gamma\gamma + 1\mu$   
selection

After  $\gamma\gamma + 1\mu$   
selection

# CR: High sideband mass Kinematic Distribution (2022-2024)

What changes vs. Low-SB:

- Green** ( $\gamma\gamma$ +jets) becomes visible again in the stack the  $m_{\gamma\gamma} > 200$  GeV window has a larger continuum contribution
- Orange** ( $t\bar{t}\gamma\gamma$ ) essentially disappears top-pair diphoton dies above 200 GeV
- Purple** (Single Higgs) is invisible no SM Higgs contribution this far from 125 GeV

Before  $\gamma\gamma + 1\mu$   
selection

After  $\gamma\gamma + 1\mu$   
selection

# SR: Kinematic Distributions (2022-2024)

- $V\gamma\gamma$  dominates strongly
- $\gamma\gamma$ +jets contributes but suppressed by the muon requirement
- $t\bar{t}\gamma\gamma$  and Single Higgs are minor contributors

Before  $\gamma\gamma + 1\mu$   
selection

After  $\gamma\gamma + 1\mu$   
selection

# Key Conclusions: Kinematic Distributions

## CR: Low-mass sideband

$$105 < m_{\gamma\gamma} < 120 \text{ GeV}$$

- Data/MC flat within uncertainty across all  $p_T, \eta, \phi$  variables ( $\gamma\gamma, \gamma_1, \gamma_2, \mu$ )
- $V\gamma\gamma$  dominates the SF-corrected background composition
- No evidence of shape mismodelling after SF correction

## VR: High-mass sideband

$$m_{\gamma\gamma} > 200 \text{ GeV}$$

- $\gamma\gamma$ +jets dominates before muon selection; agreement holds without large deviations
- Validates that the CR-derived SF extrapolates across the sideband
- Acts as an independent cross-check, not used in the SF fit

## SR (blinded)

$$130 < m_{\gamma\gamma} < 200 \text{ GeV}$$

- $1\mu + 0\tau$  selection sharply suppresses  $\gamma\gamma$ +jets ( $\approx 1000\times$  reduction from initial to final cutflow step)
- $V\gamma\gamma$  becomes the dominant background after lepton/tau veto

**Cross-cutting:**  $\Delta R(\gamma\gamma, \mu)$  and  $|\Delta\phi(\mu, \text{MET})|$  show the muon is well-separated from the diphoton system in all regions, consistent with the expected topology and not suggestive of photon-conversion or FSR-dominated configurations..

# DATA/MC AGREEMENT

## Kinematics checked (CR, 2022–2024 combined)

- Diphoton system:  $p_T(\gamma\gamma)$ ,  $\eta(\gamma\gamma)$ ,  $\phi(\gamma\gamma)$
- Leading/sub-leading photons:  $p_T(\gamma_1)$ ,  $p_T(\gamma_2)$ ,  $\eta(\gamma_{1,2})$ ,  $\phi(\gamma_{1,2})$
- Muon:  $p_T(\mu)$ ,  $\phi(\mu)$ ,  $\eta(\mu)$
- Correlation / MET:  $\Delta R(\gamma\gamma, \mu)$ ,  $|\Delta\phi(\mu, MET)|$ ,  $MET$  ( $E_T$ )

## Findings

- After applying the combined  $\gamma\gamma + 1\mu$ -derived scale factor (SF =  $1.6401 \pm 0.1018$ ) to  $V\gamma\gamma/t\bar{t}\gamma\gamma$ , Data/MC is consistent with unity within statistical uncertainty across all distributions
- No significant shape mismodelling in any variable ratio panels are flat and stable across  $p_T$ ,  $\eta$ ,  $\phi$
- High-mass sideband (VR,  $m_{\gamma\gamma} > 200 \text{ GeV}$ ) serves as an independent validation: agreement here confirms the low-mass-derived SF generalises across the sideband

## Caveat under investigation

Per-year breakdown shows the 2024 (mc23e)  $\gamma\gamma$ +jets yield/luminosity in the sideband is anomalously low relative to 2022/2023 (0.1583 vs.  $\approx 0.54$ – $0.58 \text{ fb}^{-1}$ , see backup).

Currently does not bias the combined SF beyond its quoted 6.2% uncertainty, but is being followed up.

## Signal region

- SR is used to study and characterise MC background shapes/normalisation; data in the SR remains blinded pending unblinding

# SUMMARY AND FUTURE WORK

---

## Summary

- Established a  $\gamma\gamma + 1\mu + 0\tau$  event selection for a model-independent search, using the 2HDM+S ( $m_H = 250 \text{ GeV}$ ,  $m_S \approx 152 \text{ GeV}$ ) and Higgs Triplet Model as benchmark scenarios to guide the analysis, based on  $\mathcal{L} = 163.9 \text{ fb}^{-1}$  of Run 3 data (mc23a+d+e).
- Derived a data-driven scale factor for the irreducible  $V\gamma\gamma / t\bar{t}\gamma\gamma$  backgrounds from the  $\gamma\gamma+1\mu$  sideband: combined SF =  $1.6401 \pm 0.1018$  (6.2% uncertainty)
- Demonstrated good Data/MC agreement across CR and VR kinematic distributions after SF correction, with flat ratio panels and no significant shape mismodelling
- Characterised the blinded SR cutflow:  $1\mu + 0\tau$  selection suppresses  $\gamma\gamma$ +jets by  $\approx 1000\times$ , leaving  $V\gamma\gamma$  as the dominant background
- Identified an anomalously low 2024 (mc23e)  $\gamma\gamma$  +jets sideband yield, currently within the quoted SF uncertainty but under investigation

## Future Work

- Resolve the anomalous 2024 (mc23e)  $\gamma\gamma$ +jets sideband yield and confirm its impact on the combined scale factor
- Complete outstanding signal sample requests ( $\gamma\gamma + 1\ell$ ,  $\gamma\gamma + 2\ell$ ) to extend coverage beyond the  $\gamma\gamma\tau\tau$  benchmark
- Extend background estimation: closure tests, additional single-Higgs processes, and cross-checks against ANA-HDBS-2019-04-INT1
- Work on Muon working point optimization, Explore the significance Z of the available WPs.
- Build on DSCB and background modelling, and spurious signal studies.
- Perform Fake factor Studies.

DO NOT  
GO GENTLE  
INTO THAT  
GOOD NIGHT.

Poem by Dylan Thomas

## 2. Region Definition

The following WP were used :

- 1. Medium\_PflowLoose\_VarRad
- 2. Tight\_NonIso

Region definitions:

- A = Passes Medium ID & Tight Iso
- B = Fails Medium ID & Passes Tight Iso
- C = Passes Medium ID & Fails Tight Iso
- D = Fails Medium ID & Tight Iso

## 3. Yield Calculation

- Fake Muon = Yield in region (B \* C) / D
- yyjets is enriched in fakes so we ignore it.
- Prompt MC = Signal + Vyy + ttyy + Single H
- If (Data - Prompt MC) < 0. Consider the yield to be 0 in the region.

## 4. Error Calculation

- Relative poisson uncertainty :  $\frac{\sigma_{data}}{N} = \frac{1}{\sqrt{N}}$
- Weighted MC uncertainty :  $\sigma_{MC} = \sqrt{\sum_i w_i^2}$
- Uncertainty in region yields :  $\sqrt{\sigma_{data}^2 + \sigma_{MC}^2}$
- Error in fake prediction :  $N_{fake} \times \sqrt{(\frac{\sigma_B}{B})^2 + (\frac{\sigma_C}{C})^2 + (\frac{\sigma_D}{D})^2}$
